Commisurotomy patient has no trouble finding by blind touch among objects screened from right. If the sample object touched flashed on the screen by from among a series of items screened from sight—provided the left hand is used for things seen in the left half field of vision and vice versa. If the right hand is used, the items are recognized but the perceiving hemisphere doesn’t know what it is looking for. The feedback from the exploring hand. Hence the visual and tactile information never get together and the performance fails.
